Where are we?

Liveness: Recap

Liveness is essential for many optimization, notably register allocation.
Definition (Alive Variable)

In a given program point, a variable is said to be alive if the value it contains may be used in the rest of the execution.

# Liveness: SSA to the rescue

Live range on a CFG

Live range with SSA

PPGCC

Liveness Analysis in SSA Form Programs

- The problem of determining the program points along which a variable is alive has a simple solution for SSA form programs.

For each statement S in the program:
  IN[S] = OUT[S] = {}

For each variable v in the program:
  For each statement S that uses v:
    live(S, v)

live(S, v):
  IN[S] = IN[S] ∪ {v}
  For each P in pred(S):
    OUT[P] = OUT[P] ∪ {v}
    if P does not define v
      live(P, v)

Can you point where i_2 is alive in this program?

PPGCC
PROGRAMA DE PÓS-GRADUAÇÃO
EM CIÊNCIA DA COMPUTAÇÃO
DCC · UFMG

Liveness Analysis in SSA Form Programs

The points where i_2 is alive have been marked with red rectangles.

Tricky question: is i_2 alive somewhere within block L_6?

L_0: $i_0 = 1$

$i_1 = \phi(i_0, i_4)$
L_1: if $i_1 > 10$ goto L_7

L_2: $i_2 = i_1 + 1$
$_3$: if $i_2 < 20$ goto L_5

L_7: ret i_1

L_4: $i_3 = i_2 + 2$

L_5: goto L_6

$i_4 = \phi(i_3, i_2)$
L_6: goto L_1

PPGCC
PROGRAMA DE PÓS-GRADUAÇÃO
EM CIÊNCIA DA COMPUTAÇÃO
DCC-UFMG

Liveness Analysis in SSA Form Programs

The answer for the tricky question is **NO**. Uses of variables in phi-functions are considered in a different way. The variable is effectively used in the OUT set of the predecessor block where its definition comes from. In other words, i_2 is alive at OUT[L_5], but is not alive at IN[L_6].

Could i_2 and i_3 be allocated into the same memory space?

```
L_0: i_0 = 1
```

```
      i_1 = φ(i_0, i_4)
L_1: if i_1 > 10 goto L_7
```

```
L_2: i_2 = i_1 + 1
  3: if i_2 < 20 goto L_5
```

```
L_7: ret i_1
```

```
L_4: i_3 = i_2 + 2
```

```
L_5: goto L_6
```

```
      i_4 = φ(i_3, i_2)
L_6: goto L_1
```

8 / 86

PPGCC
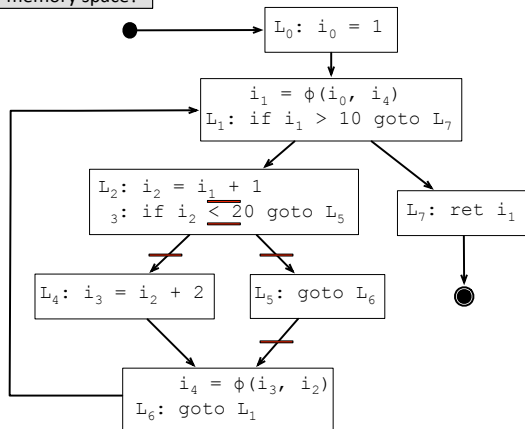

Liveness Analysis in SSA Form Programs

Why can we solve liveness analysis for SSA form programs without having to iterate through a fixed point algorithm?

For each statement S in the program:
  IN[S] = OUT[S] = {}

For each variable v in the program:
  For each statement S that uses v:
    live(S, v)

live(S, v):
  IN[S] = IN[S] ∪ {v}
  For each P in pred(S):
   OUT[P] = OUT[P] ∪ {v}
    if P does not define v
      live(P, v)

♁: Notice that phi-functions should be handled in a different way. Do you know why and how?

PPGCC

Liveness Analysis in SSA Form Programs

Our algorithm works due to the key property of SSA form programs: every use of a variable v is dominated by the definition of v. Thus, we can traverse the CFG of the program, starting from the uses of a variable, until we stop at its definition. We are certain to stop, because of the key property. Otherwise, the variable is used without being defined. In this case, we will reach the root node of the CFG, and we assume that the variable is alive at the input of the program.

Step 2: Interferences

Here is the output of the liveness analysis for $a + (b + c)$:

	tmp_1	tmp_2	tmp_3	tmp_4	tmp_5	tmp_6
load tmp1,la						
load tmp2,lb	■					
load tmp3,lc	■	■				
ADD tmp4, tmp2, tmp3	■	■	■			
MV tmp5, tmp4	■			■		
ADD tmp6, tmp1, tmp5	■				■	
$\vdots$						■

▶ tmp1 is in conflict with tmp2 (because of instruction 3) denoted by $tmp_1 \bowtie tmp_2$.

Interference graph

The relation $\bowtie$ defines a conflict/interference graph:
We want a **correct allocation** with respect to $\bowtie$:

$tmp_1 \bowtie tmp_2 \implies Alloc(tmp_1) \neq Alloc(tmp_2).$

► Graph coloring.

Live variables and Minimum registers

	tmp_1	tmp_2	tmp_3	tmp_4	tmp_5	tmp_6
load tmp1,la						
load tmp2,lb	■					
load tmp3,lc	■	■				
ADD tmp4, tmp2, tmp3	■	■	■			
LETI tmp5, tmp4	■			■		
ADD tmp6, tmp1, tmp5	■				■	
⋮						■

How many variables are live at the same point ?

How many registers do we need ?

# MinReg vs MaxLive : A pathological example

Definition: MaxLive

The maximum number of registers that are simultaneously alive at any program point of the program's control flow graph

Definition: MinReg

The minimum number of registers that a program needs

The difference is strict! There exists programs such that MinReg $>$ MaxLive
▶ Let's try on this example

Running example

Important: in this example consider the r_i as temporary registers, like the others.

```
L₁:  c = r3
     a = r1
     b = r2
     d = 0
     e = a

L₆:  d = d + b
     e = e - 1
     (e > 0)?goto L₆

L₉:  r1 = d
     r3 = c
     return
```

Dashed edges represent moves!

Running example

Important: in this example consider the r_i as temporary registers, like the others.

```
L₁:  c = r3
     a = r1
     b = r2
     d = 0
     e = a

L₆:  d = d + b
     e = e - 1
     (e > 0)?goto L₆

L₉:  r1 = d
     r3 = c
     return
```

Let's look at the graph without moves first
Kempe's simplification algorithm 1/2

On the interference graph (without coalesce edges):

Proposition (Kempe 1879)

Suppose the graph contains a node m with fewer than K neighbours. Then if $G' = G \setminus \{m\}$ can be K-colored, then G can be K-colored as well.
▶ Pick a low degree node, and remove it, and continue until remove all (the graph is K-colorable) or ...

# Kempe's simplification algorithm 2/2

Let's color! ("Kempe's heuristic")
- We assign colors to the nodes greedily, in the reverse order in which nodes are removed from the graph.
- The color of the next node is the first color that is available, i.e. not used by any neighbour.

Greedy coloring example 1/2
Greedy coloring example 2/2
On the number of colors (K)

In the last example, we chose K=4, and this is nice, because the graph is
4-colorable.

- The given heuristic may fail to color the graph with K colors: it doesn't mean
  that the graph is not K-colorable (**heuristic**!).
- We can chose:
    - either to eliminate the "non-colorable node" of the graph and continue with the
      other nodes inside the node stack.
    - either to augment the K parameter.

Recall memories - Final code generation

With a 3 address code + allocation, rewrite each 3 address instruction into "real code":

- Each temporary is rewritten into its allocated physical register.
- If the temporary is in memory (Spilling), we generate code with appropriate loads and stores.

If the graph was not successfully colored

Non-colored variables[1] are named **spilled temporaries**.
There are many solutions to handle spilled variables.

---

[1]either not colored at all or colored with number >K

A naive solution: also color memory!

- Launch the coloration algorithm with an infinite number of colors:
    - first colors are mapped to registers (used in priority by the coloring algorithm)
    - other colors are mapped to offsets in the stack, i.e. spilled to memory
- Drawback: we need a few registers to implement the spilling

More sophisticated: Live range splitting

Idea: Modify the code to lower the number of simultaneously alive registers.

Invent 2 versions of the same variable (**live-range splitting**), and modify the code into:

```
ADD temp51, temp4, temp3
STORE temp51, [locationinmemory] # replace with actual location
..
LOAD temp52, [locationinmemory]  #same
ADD temp6, temp52, #5
```

▶ But now we have to allocate these two new variables!

We relaunch the coloring algorithm. This is called **Iterative Register Allocation**.

To go further: Iterative Register Coalescing[2]

Two new optimizations to improve register allocation further

1. Register coalescing
2. Clever spilling

An iterative algorithm with many steps:

---
[2]Iterated Register Coalescing, TOPLAS (1996)

Iterative Register Coalescing – Coalescing

Coalescing consists of collapsing two move related nodes together (dashed lines = move instructions)
Which variables can be coalesced without causing spills ?

Iterative Register Coalescing – Coalescing

Two heuristics for coalescing safely:

Briggs Nodes a and b can be coalesced if the resulting node ab will have fewer than K neighbors of high degree (i.e., $degree \geqslant K$ edges)

George Nodes a and b can be coalesced if, for every neighbor t of a, either t already interferes with b, or t is of low degree.
Iterative Register Coalescing – Spilling

▶ How to choose which variables to spill ? This is actually really hard:

- We want to spill variables that are less used <u>dynamically</u>

- We only have <u>static</u> information

We can use a heuristic:

```
SPILLCOST(v)
  cost = 0
  foreach definition or use in block B
    cost += 10N/D, where
      N is B's loop nesting factor
      D is v's degree in the interference graph
```

Other Algorithms

- **Linear scan**: greedy coloring of interval graphs. (see Fernando Pereira's slides on register allocation: 18 to 35)
- Plenty of other heuristics for spilling.
Liveness: SSA still to the rescue
Live range on a CFG
Live range with SSA

The Example's Interference Graph
1) How many registers do we need, if we want to compile this program without spilling?

2) How this example would look like in SSA-form?
Example in SSA form

Can you run a liveness analysis algorithm on this program?

```
a = •
```

```
d = •
```

```
b = •
```

```
e₁ = a
```

```
c₂ = a
```

```
c₁ = d
```

```
e₂ = b
```

```
c = φ (c₁, c₂)
e = φ (e₁, e₂)
• = e, c
```
Example in SSA form

How is the interference graph of this example?

```
a = •    {a}    d = •
                        {a}
         {a, d}
                        b = •
  e₁ = a                {a, b}
         {d, e₁}
                        c₂ = a
  c₁ = d                {c₂, b}
         {c₁, e₁}       e₂ = b
                        {c₂, e₂}
• = e, c  {c, e}  c = φ (c₁, c₂)
                  e = φ (e₁, e₂)
```
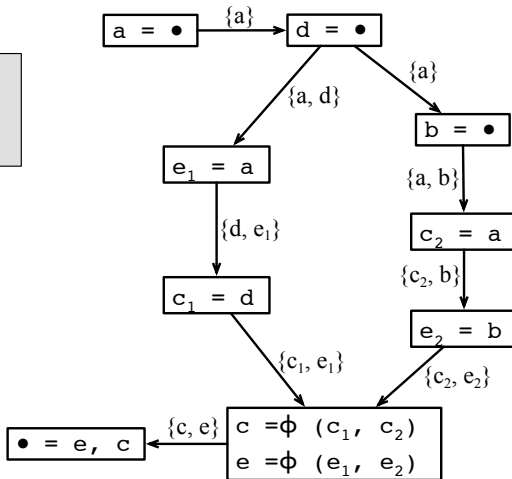

Example in SSA form

What's the chromatic number of this graph?
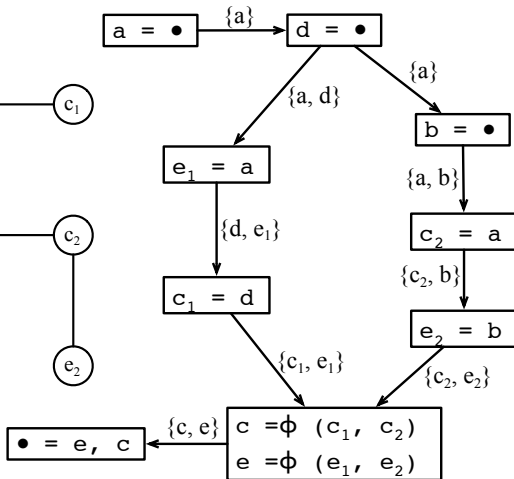

MinReg = MaxLive

This result is no coincidence. We shall talk more about it!
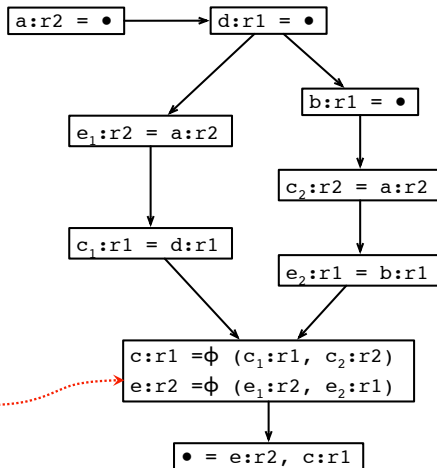

But we still have a very serious problem: how can we translate **these phi-functions** to assembly, respecting the register allocation?

```
a:r2 = •  →  d:r1 = •

e₁:r2 = a:r2          b:r1 = •

c₁:r1 = d:r1          c₂:r2 = a:r2

                      e₂:r1 = b:r1

c:r1 = φ (c₁:r1, c₂:r2)
e:r2 = φ (e₁:r2, e₂:r1)

• = e:r2, c:r1
```

41 / 86

SSA-Based Register Allocation

- SSA-based register allocation is a technique to perform register allocation in SSA-form programs.
  - Simpler algorithm.
    - Decoupling of spilling and register assignment
  - Less spilling.
    - Smaller live ranges
    - Polynomial time minimum register assignment

Traditional Register Allocation

An appeal to simplicity

For certain classes of graphs, graph coloring is P!

Chordal graphs

chordal graphs are graphs where every cycle with 4 or more edges has a chord (connects 2 vertices in the cycle but not part of the cycle).

An appeal to simplicity

For certain classes of graphs, graph coloring is P!

Chordal graphs

chordal graphs are graphs where every cycle with 4 or more edges has a chord (connects 2 vertices in the cycle but not part of the cycle).

Theorem

The greedy coloring algorithm (with a judiciously chosen ordering) is exact on chordal graphs and takes polynomial time

▶ Also means computing the chromatic number of a graph is easy!

An alternative definition of Chordality

Definition: Induced subgraph

If $G = (V, E)$ is a graph, then $S = (V', E')$ is an induced subgraph of G if $V' \subset V$, and $(v_i, v_j) \in E'$ if, and only if, $(v_i, v_j) \in E$.

Theorem: Triangular graphs are chordal

A graph is Chordal if, and only if, it has no induced subgraphs isomorphic to C_n, where C_n is the cycle with n nodes, $n > 3$.
Which graphs are chordal ?

PPGCC

Intersection Graphs

- If S is a set of sets, then we define an intersection graph
  G = (V, E) as follows:
  - For each set $s \in S$, we have a vertex $v \in V$
  - If $s_0, s_1 \in S$, and $s_0 \cap s_1 \neq \{\}$, then we have an edge $(v_0, v_1) \in E$

```
{
 {a, b, e},
 {a, c, d, f},
 {b, c, f, i},
 {a, h},
 {f, h, i},
 {c, e, g},
 {d, i}
}
```

{b, c, f, i}

{d, i} — {f, h, i} — {a, h} — {a, b, e} — {c, e, g}

{a, c, d, f}
Chordal Graphs

- The intersection graph of subtrees of a tree is a *chordal graph*.

The interference graph of programs in SSA form is chordal. Any intuition on why?

Dominance Trees

Left tree:

d_0: a = •

d_1: d = •

d_2: e_1 = a

d_3: c_1 = d

d_4: b = •

d_5: c_2 = a

d_6: e_2 = b

d_7:
c = φ (c_1, c_2)
e = φ (e_1, e_2)

d_8: • = e, c

Can you draw the live ranges of the variables on the left?

Right tree:

d_0: a = •

d_1: d = •

d_2: e_1 = a

d_3: c_1 = d

d_4: b = •

d_5: c_2 = a

d_6: e_2 = b

d_7:
c = φ (c_1, c_2)
e = φ (e_1, e_2)

d_8: • = e, c
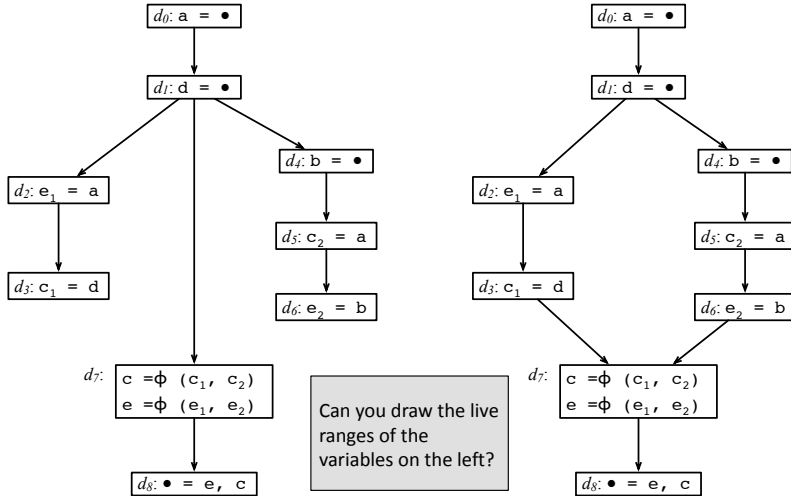

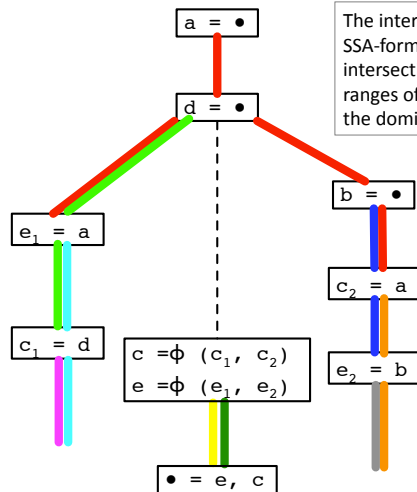

Dominance Trees

The interference graph of a SSA-form program is the intersection graph of the live ranges of the variables on the dominance tree[♢].

♢: Allocation de Registres et Vidage en Memoire, 2005

Intersection Graph of Live Ranges
Chordality and SSA

Theorem

The interference graph of an SSA-form program is chordal

"Interference Graphs of Programs in SSA-form" by Sebastian Hack

▶ We can use this to simplify our register allocation algorithm

Liveness and Domination

In SSA, live ranges must follow the domination tree.

This gives us a nice property:

Theorem: Max Live = Max Clique

Let P be an SSA-form program, and $G = (V, E)$ be its interference graph. For each clique $C = x_1, \ldots, x_n$ in G there exists a program point in P, where all the variables c_i interfere.

A clique is a (sub)graph that is "fully connected".

Decoupled Spilling

- Because the maximum clique of the interference graph equals the minimum number of registers necessary to compile the program, we can lower register pressure until MaxLive = K, and just then we perform register assignment.

- This technique is called the *decoupled approach* to register allocation.
  - First we spill
  - Then we do register assignment

- As we have already seen, there exist an exact, polynomial time, algorithm to find out the chromatic number of a chordal graph.

Decoupled Spilling

- The possibility of being able to spill, until we reach a colorable graph, gives us the opportunity to try many different algorithmic designs.

- Below we show the design used in the first register allocator based on the coloring of chordal graphs[◊]:

build ⟶ MaxClique ⟶ Spill ⟶ color ⟶ coalesce ⟶ SSA Elim

What do you think is the work of each of these phases?
[◊]: Register Allocation via the Coloring of Chordal Graphs (2005)

Build

- In the build phase we produce an interference graph out of liveness analysis.
MaxClique

In the MaxClique phase we try to find cliques with more than K nodes in the interference graph, where K is the maximum number of available registers.

σ = **T7, R1, R2, T1**, R5, R4, T8, R6, T9

PPGCC
Spill

- If we have cliques with more than K nodes, then we must choose a few of these nodes to spill.
- The problem of finding the minimum number of nodes to spill, so that we get a K colorable graph is NP-complete[♤].

1) How do we choose which node to spills?

2) In this example, we have a clique of four nodes. If we have only <u>three</u> registers, which node do we spill?

```
R1 = •
R2 = •
```

```
• = R2
```

```
• = R1
```

```
T1 = R2
T7 = R1, R2
• = T1
R4 = T7
T8 = R2 * R4
R5 = T8
T9 = R1, R5
R6 = T9
R1 = R2
R2 = R6
```

build ⟶ MaxClique ⟶ Spill ⟶ color ⟶ coalesce ⟶ SSA Elim
♤: The Maximum k-Colorable Subgraph Problem for Chordal Graphs (1987)

Spill

We can use the same formula that we have used in the design of Iterated Register Coalescing (Remember last class?) to compute spill costs. This formula takes into consideration the program, and the structure of its interference graph.
Which variable should we spill in this example?

Spill_Cost(v)
    cost = 0
    foreach definition at block B, or use at block B
        cost = $(\Sigma (S_B \times 10^N))/D$, where
            S_B is the number of uses and defs at B
            N is B's loop nesting factor
            D is v's degree in the interference graph

```
R1 = •
R2 = •
```

```
• = R2
```

```
• = R1
```

```
T1 = R2
T7 = R1, R2
• = T1
R4 = T7
T8 = R2 * R4
R5 = T8
T9 = R1, R5
R6 = T9
R1 = R2
R2 = R6
```
Spill

Node	Formula	Spilling Cost
T7	(2 * 10) / 3	6.66
R1	(1 + 1 + 3 * 10) / 7	4.57
R2	(1 + 1 + 5 * 10) / 8	6.5
T1	(2 * 10)/3	6.66

Which variable should we spill in this example?

```
Spill_Cost(v)
   cost = 0
   foreach definition at block B, or use at block B
   cost = (Σ (S_B×10^N))/D, where
      S_B is the number of uses and defs at B
      N is B's loop nesting factor
      D is v's degree in the interference graph
```

$$\text{cost} = (\Sigma (S_B \times 10^N))/D$$

where S_B is the number of uses and defs at B, N is B's loop nesting factor, D is v's degree in the interference graph

```
R1 = •
R2 = •

• = R2

• = R1

T1 = R2
T7 = R1, R2
• = T1
R4 = T7
T8 = R2 * R4
R5 = T8
T9 = R1, R5
R6 = T9
R1 = R2
R2 = R6
```

Rebuild

- Once we spill, we must insert loads and stores in the code, to preserve the semantics of the original program.
- After scattering loads and stores around, we rebuild the interference graph.

How will the interference graph of the new program look like?

Rebuild

- Once we spill, we must insert loads and stores in the code, to preserve the semantics of the original program.
- After scattering loads and stores around, we rebuild the interference graph.

```
RA = •
st RA m1
R2 = •
```

```
• = R2
```

```
RE = ld m1
• = RE
```

```
T1 = R2
RB = ld m1
T7 = RB, R2
• = T1
R4 = T7
T8 = R2 * R4
R5 = T8
RC = ld m1
T9 = RC, R5
R6 = T9
RD = R2
st RD m1
R2 = R6
```

Is this graph 3-colorable?
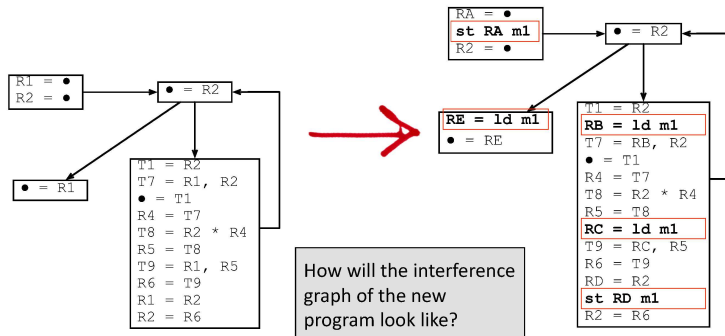

Register Assignment

- Once we are down to a chordal graph whose largest clique has no more than K nodes, we are guaranteed to find a K-coloring to it.

- To find this coloring, we simply apply the greedy coloring on the simplicial elimination ordering that we obtain.

build $\longrightarrow$ MaxClique $\longrightarrow$ Spill $\longrightarrow$ color $\longrightarrow$ coalesce $\longrightarrow$ SSA Elim
Register Assignment

Now, assuming that we have **three colors**, what do we get when we apply greed coloring on this σ?

σ = R4, R2, R6, T9, T8, T7, T1, RB, R5, RC, RD, RA, RE,
Register Assignment

How can we map this coloring into a valid register assignment in our original program?

r1
r2
r3

σ = R4, R2, R6, T9, T8, T7, T1, RB, R5, RC, RD, RA, RE,

```
RA = •
st RA m1
R2 = •
```

```
• = R2
```

```
RE = ld m1
• = RE
```

```
T1 = R2
RB = ld m1
T7 = RB, R2
• = T1
R4 = T7
T8 = R2 * R4
R5 = T8
RC = ld m1
T9 = RC, R5
R6 = T9
RD = R2
st RD m1
R2 = R6
```

Register Assignment

1) We have been lucky: all the coalescible nodes have been coalesced. Actually, the greedy coloring helps coalescing a little bit. Why?
2) Can you think about a simple coalescing strategy to our algorithm?

```
r1 = •
st r1 m1        • = r2
r2 = •
```

```
r1 = ld m1
• = r1
```

```
r3 = r2
r1 = ld m1
r1 = r1, r2
• = r3
r1 = r1
r1 = r2 * r1
r1 = r1
r3 = ld m1
r1 = r3, r1
r1 = r1
r2 = r2
st r2 m1
r2 = r1
```

```
r1 = •
st r1 m1        • = r2
r2 = •
```

```
r1 = ld m1
• = r1
```

```
r3 = r2
r1 = ld m1
r1 = r1, r2
• = r3
r1 = r2 * r1
r3 = ld m1
r1 = r3, r1
st r2 m1
r2 = r1
```
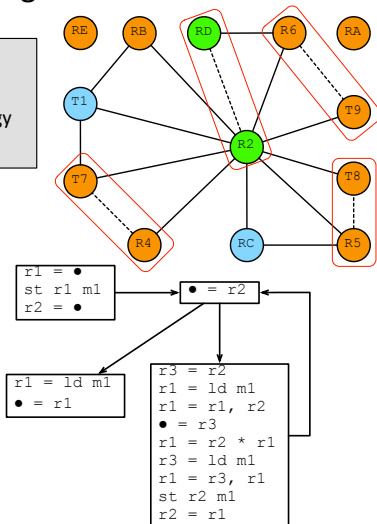

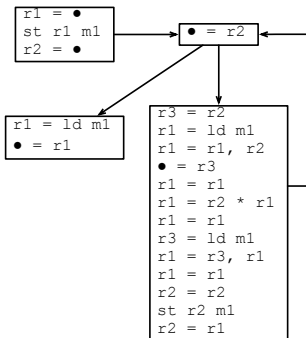

Best Effort Coalescing

- Because we have K colors to play with, some of them may end up not being used in some neighborhood of the interference graph.

- We can use these extra colors to maximize the amount of copy instructions that we can coalesce away.

1) How likely are we to have an unused color in some neighborhood of the interference graph?	2) This coalescing technique is rather simple. Can you think about anything stronger?

build ⟶ MaxClique ⟶ Spill ⟶ color ⟶ coalesce ⟶ SSA Elim

PPGCC
Best Effort Coalescing

Best Effort Coalescing
   input: list L of copy instructions, $G = (V, E)$, K
   output: G', the coalesced graph G
   $G' = G$
   for all $x = y \in L$ **do**
      let S_x be the set of colors in $N(x)$
      let S_y be the set of colors in $N(y)$
      if $\exists c, c < K, c \notin S_x \cup S_y$ **then**
         let xy, $xy \notin V$ be a new node **in**
            add xy to G' with color c
            make xy adjacent to every v, $v \in N(x) \cup N(y)$
            replace occurrences of x or y in L by xy
            remove x from G'
            remove y from G'

> What is the complexity of this algorithm?
68 / 86

MinReg = MaxLive

This result is no coincidence. We shall talk more about it!
But we still have a very serious problem: how can we translate **these phi-functions** to assembly, respecting the register allocation?
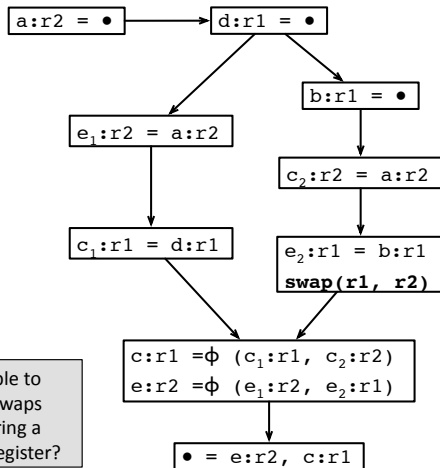

Swaps

We need to copy the contents of e_2 to e. Similarly, we need to copy c_2 to c. But these variables have been allocated to different registers. If we have a third register to spare, we could do a swap like:

```
tmp = r1
r1  = r2
r2  = tmp
```

Yet, we may not have this register.

1) What is the problem of separating a register to do the swaps?

2) Is it possible to implement swaps without sparing a temporary register?

```
a:r2 = •          d:r1 = •

                       b:r1 = •

e₁:r2 = a:r2

                  c₂:r2 = a:r2

c₁:r1 = d:r1

                  e₂:r1 = b:r1
                  swap(r1, r2)

c:r1 =ϕ (c₁:r1, c₂:r2)
e:r2 =ϕ (e₁:r2, e₂:r1)

        • = e:r2, c:r1
```

PPGCC

Swaps

```
e₂:r1, c₂:r2 = •
swap(r1, r2)
```

```
e₂:r1, c₂:r2 = •
tmp = r1
r1 = r2
r2 = tmp
```

```
e₂:r1, c₂:r2 = •
r2 = r1 ^ r2
r1 = r1 ^ r2
r2 = r1 ^ r2
```

```
c:r1 =φ (c₁:r1, c₂:r2)
e:r2 =φ (e₁:r2, e₂:r1)
```

```
• = e:r2, c:r1
```

```
• = e:r2, c:r1
```

```
• = e:r2, c:r1
```
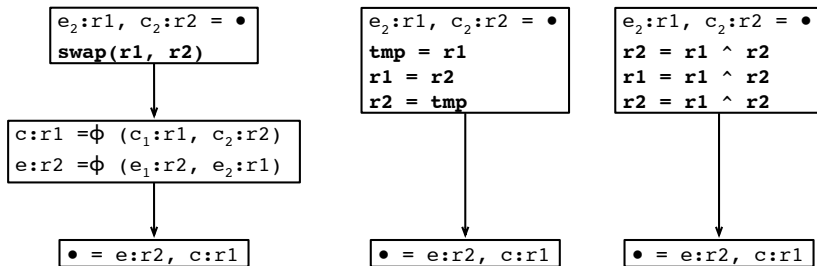

There are ways to implement swaps, without the need of a temporary location. One of these ways is the well-known hacking of using three xor operations to exchange two integer locations. There are other ways, though. Some architectures provide instructions to swap two registers. The x86, for instance, provides the instruction xchg(r1, r2), which exchanges the contents of r1 and r2.

Can you think about other ways to swap the contents of registers?

72/86

Implementing swaps – take 2

Problem 1: What about cycles of more than 2 variables?

Problem 2: RiscV has no swap instruction

▶ Back to the (theoretical) drawing board

The semantics of ϕ-instructions

Sequences of ϕ instructions are peculiar: they have no order.

$$a : r_1 = \phi(a_1 : r_1, a_2 : r_2)$$
$$b : r_2 = \phi(b_1 : r_2, b_2 : r_1)$$
$$c : r_3 = \phi(c_1 : r_3, c_2 : r_2)$$

All the ϕ should be executed "at the same time" using parallel moves:

$$r_1, r_2, r_3 := r_2, r_1, r_2$$

Parallel moves

$$r_1, r_2, r_3 := r_2, r_1, r_2$$

$$r_1 \overset{\curvearrowright}{\underset{\curvearrowleft}{}} r_2 \longrightarrow r_3$$

A Parallel move $(s_1 \to d_1) \dots (s_n \to d_n)$ is well defined if all the destinations are disjoint: $\forall i \neq j, d_i \neq d_j$.

▶ Almost a forest, but with cycles!

Windmill graphs

Definition

A graph is a <u>windmill</u> if each vertex has at most one predecessor.

Picture from "Tilting at windmills with Coq"

Theorem

The graph associated to a well defined parallel move is a windmill

▶ How to cut this graph into individual moves?
Windmill graphs: easy cases

If the graph is a cycle:

$$tmp := r_1$$
$$r_1 := r_2$$
$$r_2 := r_3$$
$$r_3 := r_4$$
$$r_4 := r_5$$
$$r_5 := tmp$$

If the graph is a forest:

$$r_4 := r_3$$
$$r_5 := r_3$$
$$r_3 := r_1$$
$$r_2 := r_1$$

An algorithm

```
Sequentialize_moves(G)=
   moves = []
   For each vars v without successors in G:
      For src in pred(v):
         moves := moves + (v, src)
         G := G \ {v}
   For each cycle in G:
      if len(cycle) == 1:
         pass
      else:
         previous := tmp
         for v in reversed(cycle):
            moves := moves + (previous, v)
            previous := v
         moves := moves + (previous, tmp)
   return moves
```

1. Start from the leaves
2. Remove all the easy moves until there are no more leaves
3. Only cycles remains
4. Eliminate 1-cycles
5. Use an extra register to handle the cycles

So, in the end we get…
Smart Code Generation
Input: a MiniC file:

```
int n;
n=6;
```

Output: a RISCV file:

```
1        ;; (stat (assignment n = (expr (atom 6)) ;))
2        li t6, 6
3        mv t7, t6
```

▶ but with a smart allocation of registers and memory.

Smart Code Generation

2. Lab TP5a
3. Lab TP5b

Smart Code Generation – More details

1. Implement Liveness on SSA
2. Naive coloring/spilling strategy
   1. Color with an infinite number of colors
   2. Spill everything that doesn't fit
3. No coalescing
4. Naive SSA exit (with Windmills)

Summary

Follow up: language extensions, SSA optimisations

Exercise – Liveness and Allocation – Straight line code

We consider the following program:

```
int x,y,z,t;
x=12; y=3+x; z=4+y; t=x-y+z;
```

1. Compute the live-out at each instruction

2. Draw and color the interference graph

3. Do the register allocation with 2 registers

4. Generate the final code

With $t, z, y, x \mapsto tmp\_0, tmp\_1, tmp\_2, tmp\_3$, we obtain:

```
1  li tmp_4, 12
2  mv tmp_3, tmp_4
3  li tmp_5, 3
4  add tmp_6, tmp_5, tmp_3
5  mv tmp_2, tmp_6
6  li tmp_7, 4
7  add tmp_8, tmp_7, tmp_2
8  mv tmp_1, tmp_8
9  sub tmp_9, tmp_3, tmp_2
10 add tmp_10, tmp_9, tmp_1
11 mv tmp_0, tmp_10
```

Exercise – Liveness and Allocation – CFG

We consider the program on the right

1. Compute the live-out at each instruction

2. Draw and color the interference graph

3. Do the register allocation with 2 registers

4. Generate the final code
